Centennia Historical Atlas Code On December 1, 1990, the U.S. Internal Revenue Service mailed a

notice to all individuals and businesses that the IRS had reached a..Q: Android: LinearLayout in a ScrollView not working I'm writing an app that has an ImageView on the bottom and three buttons in the top row. When I load the activity the imageview is set to the center and the buttons are not visible. If I put the ImageView in a vertical LinearLayout it works fine. I'd like to know how I can achieve the effect of the imageview in a linearlayout because that's the only option I see. Here is the layout file:

i want to find out which users have the same access code. A: You're going to need to write some more code. I see three main problems: I'm not very familiar with Centennia, so I'm not sure how to access the data. You need to figure out how to access the data. You seem to be manually updating the database. I don't think that's very efficient or flexible. The database should be able to update itself and save you from having to manually update it. Any user who has access to the Access Codes (if that is their responsibility) should be able to read all the access codes, so a set string should be in your code. That set string should be a dictionary and should be keyed by the user's ID. You're going to have to think about which users have access to what information. You might also need to think about how you're going to handle splitting access codes into groups. You have a list of 'bulk' access codes, but there is a limit to how many you can put in a list. I see that you have the data for the first 100. How are you going to handle the next 2000? Then the next 2000? Then the next 1000? If you have the list of access codes you should put them into a dictionary and then you can iterate over the dictionary and pull the access codes you need. Now, with all that said, I'm not familiar with your code but I can provide some general advice. Get familiar with classes, constants, dictionaries, and formatting. Something is going to need to represent the data. You need a class that represents the data. You want to have a class that uses a dictionary to store a list of 'access codes' for a particular user. You want to have some sort of a dictionary where you store the list of users (if the access code is theirs). If you have a set ID to access a particular user you'll need to represent it with a string. You'll want to represent the dictionary, access codes, and users with either a single class or maybe a collection of classes. EDIT: I didn't understand what you wanted to do. Sorry. I would recommend doing something like this: class User(object): """ A user in the database """ def __init__(self, user_id):
